S1 Table. Both statistical readings for every subset-paired arm comparison.
Each row is one arm comparison at the three-subset protocol. Δ is the mean difference in accuracy over the three subsets, in points, with the subset-to-subset standard deviation beside it; the paired t-test on those three differences (df = 2) is the test the paper reports. b and c count discordant test items pooled over the three subsets – items the first arm got right and the second wrong, and the reverse – and the McNemar p is computed from them. Pooling reuses the same test items three times, which is why we do not rely on it. Cells marked *excluded* fail the headroom criterion of the main text and are reported here for completeness.
